Abstract

Meso-meso linked diporphyrins ([H2Por]2) covalently functionalized soluble single-walled carbon nanotubes ([H2Por]2-SWNTs) have been successfully prepared. As a light-harvesting chromophore, meso-meso linked diporphyrins have been incorporated into a photosynthetic electron-transfer model with SWNTs as an electron-acceptor. The steady emission characteristics revealed the existence of the effective energy and electron transfer between the excited porphyrin moiety and SWNTs, and the electron transfer process was confirmed by electrochemical study. The charge separation quenching process was supported by the results of time-resolved transient absorption spectra, and the lifetime of charge-separation state was observed to be 145 ns, which was 2.5 times of that of monoporphyrin modified SWNTs (TPP-SWNTs).

1. Introduction

Carbon nanotubes are actively being investigated for producing photovoltaic and photocatalytic devices [1–6] because of their high delocalized, extended π-electron system [7,8]. Especially, most single-walled carbon nanotubes (SWNTs) have the diameter of approximately 1 nm, which results in a higher aspect ratio and a greater curvature of the sidewall. That further alters the extent of orbital overlap and the electronic density [9], and makes them be natural electron acceptor [10–12]. SWNTs have thus been widely used combining with light absorption chromophores to construct photovoltaic devices [1,13–17]. Porphyrins have been widely used combining with light absorption chromophores to construct photovoltaic devices [1,13–17]. Porphyrins are known chromophores, which play an important role in natural photosynthetic system due to their unique photophysical and electrochemical properties [18–20]. In the past decades, porphyrins have been broadly applied in the research of artificial photosynthetic mimic systems [21–29]. In view of the distinct advantages of porphyrin and SWNTs, a number of SWNTs–porphyrin nanohybrids, constructed by π–π and Van der Waals [30–34], polymer wrapping [35,36], electrostatic interaction [37–40] or covalent bond [41–46], have been built to be photoelectron transfer models. As mentioned above, porphyrins functionalized SWNTs have attracted extensive attention as excellent candidates for nanoscale photovoltaic devices. Some covalently linked porphyrin-functionalized SWNTs [42–44] have previously been synthesized in our group for the research of energy and electron transfer. We found an 86% reduction of fluorescence quantum yield in the nanohybrid employing amide linkage between SWNTs and porphyrin [43], while more than 97% reduction with a direct linkage mode [42]. Obviously, the direct linkage mode facilitated the effective energy and electron transfer between the excited porphyrin moiety and SWNTs. We report here the preparation of the meso-meso linked diporphyrin functionalized SWNTs with a direct linkage. The replacement of monoporphyrin with meso-meso linked diporphyrin can result in a broader absorption, which attributes to the excitation coupling of the porphyrin subunits [47–54]. Furthermore, meso-meso linked diporphyrin has prolonged charge-separation (CS) lifetime of porphyrin–acceptor system compared with monoporphyrin [50]. Therefore, meso-meso linked diporphyrin functionalized SWNTs ([H2Por]2-SWNTs) (Scheme 1) is rationally expected to be an improved photon-to-electron conversion system.

2. Results and discussion

2.1. Synthesis and characterization

The meso-meso linked diporphyrin functionalized SWNTs ([H2Por]2-SWNTs) was prepared by the reaction of octadecylamine modified SWNTs (ODA-SWNTs) with the corresponding diporphyrin diazonium compound generated from diporphyrin amino compound in situ (Scheme 2) [42,55]. The diporphyrin was obtained via a Suzuki-coupling reaction (Scheme 3) [56].

The Raman spectrum of [H2Por]2-SWNTs was significantly different from that of ODA-SWNTs (Fig. 1). Compared to ODA-SWNTs, more structure information could be found except for the tangential mode at ∼1590 cm−1 (G-band) and the disorder...
mode at \( \sim 1350 \text{ cm}^{-1} \) (D-band). The additional peaks at 819, 1002, 1082, 1234, 1454, and 1553 cm\(^{-1}\) could be assigned to the covalently attached porphyrin moiety [57]. Meanwhile, the FTIR spectrum of \([\text{H}_2\text{Por}]_2\)-SWNTs (see ESI, Fig. S1) exhibited the characteristic porphyrin absorptions at 3306, 3060, 1537, 1419, 1022, 792, and 684 cm\(^{-1}\). The absorption bands at 3306 and 3060 cm\(^{-1}\) could be separately assigned to the stretching vibration of the pyrrole N–H and aromatic C–H of the diporphyrins. The bands at 3343, 2921, 2850, and 1646 cm\(^{-1}\) derived from the moieties of octadecylamine. These Raman and IR data indicate a successful functionalization of SWNTs with diporphyrins.

Consisting with Raman and FTIR results, the transmission electron microscopy (TEM) images showed more direct evidence for the successful modification. Fig. 2 shows the typical surface morphology of SWNTs before and after porphyrin functionalization. The sidewall of the SWNTs was significantly roughened by the coverage of soft materials, indicating the presence of porphyrin attached to the SWNTs surface. The content of porphyrin moiety

Fig. 1. Raman spectra of [H₂Por]₂-SWNTs (A) and ODA-SWNTs (B).

in [H₂Por]₂-SWNTs nanohybrid could be estimated in the light of the elemental composition of ODA-SWNTs and [H₂Por]₂-SWNTs (Table 1), determined by X-ray photoelectron spectroscopy (XPS). The content of diporphyrin unit in [H₂Por]₂-SWNTs, one diporphyrin unit per ~600 C atoms, is similar to the content of monoporphyrin unit in TPP-SWNTs nanohybrid.

2.2. Steady state absorption spectroscopy

The steady state absorption spectrum of [H₂Por]₂-SWNTs in ODCB (Fig. 3) showed two split Soret bands (423 and 459 nm) and four Q-bands (530, 569, 601, and 662 nm). There was one more Soret band than the absorption spectrum of monoporphyrin functionalized SWNTs (TPP-SWNTs) (Fig. 3). Compared to [H₂Por]₂-ref, there were 4–7 nm red-shift for both Soret bands and Q-bands, and simultaneously with notable broadening of the Soret bands. Those reflect that the covalent bonding to SWNTs causes a change of the electronic states of diporphyrin, and there is notable electronic communication between SWNTs and diporphyrin in the ground state [58]. The absorption spectra of [H₂Por]₂-SWNTs with different concentrations were measured, and the absorption values at 419 and 459 nm were plotted against concentrations to get a standard curve (in mg L⁻¹, Fig. 4). On the basis of Beer’s law, the effective extinction coefficient of [H₂Por]₂-SWNTs was determined to be 0.03 L mg⁻¹ cm⁻¹ in accordance with the slope of the linear least-squares fit. The absorption values of [H₂Por]₂-SWNTs at different wavelengths were well in line with the correlative concentrations, proving that the solution was homogeneous. The solubility could be calculated to be 355 mg L⁻¹ according to the Beer’s law, and the solution in ODCB was stable for several months (Fig. 5). The good solubility indicates the exfoliating of nanotube bundles.

2.3. Steady state emission spectroscopy

The excited state interactions between SWNTs and diporphyrins were explored by steady state fluorescence spectra of [H₂Por]₂-ref and [H₂Por]₂-SWNTs. [H₂Por]₂-SWNTs exhibited complete fluorescence quenching (100%, Fig. 6), upon excitation of the porphyrin moiety at 419 and 453 nm. Even when the absorption of SWNTs was subtracted from the absorbance of [H₂Por]₂-SWNTs, the fluorescence also exhibited almost complete quenching (99%) (see ESI, Fig. S2). The complete luminescence quenching indicates that there is a strong interaction between the excited diporphyrin and SWNTs [42]. Possible pathways for the deactivation of excited porphyrins may be attributed to two competitive processes, energy transfer (ET) and photoinduced electron transfer (PET). The emission band of [H₂Por]₂ between 620 and 800 nm) overlaps with the absorption band of SWNTs, which enables single–single energy transfer from diporphyrin to SWNTs [59]. Nevertheless, the fluorescence quantum yield of [H₂Por]₂-SWNTs significantly decreased against increasing solvent polarity (Table 2), which indicates that the quenching process in [H₂Por]₂-SWNTs nanohybrid is mainly dominated by the excited state electron transfer, because the energy transfer commonly does not depend on solvent polarity while the electron transfer tends to be sensitive to medium effects [42,60,61].
2.4. Electrochemistry analysis

Electrochemical studies with cyclic voltammetry (CV) were performed to understand the overall redox behavior of [H₂Por]₂-SWNTs, evaluate the electronic properties of the nanohybrid, and also visualize the existence of any electronic interaction between diporphyrins and SWNTs. The CV of [H₂Por]₂-ref showed two oxidation and one reduction processes (see ESI, Fig. S3). The first reduction peak was observed at −1.57 V versus Ag/Ag⁺, and the two oxidation peaks were seen at +0.66 and +0.90 V, respectively. The redox properties of the mixture of ODA-SWNTs and [H₂Por]₂-ref (ODA-SWNTs + [H₂Por]₂-ref) did not show any significant variations compared to [H₂Por]₂-ref (Table 3). However, obvious variations were found in the oxidation and reduction potentials of [H₂Por]₂-SWNTs. The first oxidation peak was observed at +0.32 V with a cathodic shift of −340 mV, which can be attributed to the fast electron transfer in [H₂Por]₂-SWNTs as a result of limited access of the SWNTs bound redox probes to the electrode surface [63]. One more reduction peak at −0.49 V appeared in [H₂Por]₂-SWNTs, which corresponded to the reduction potential of SWNTs [63]. The change of redox properties of porphyrin moiety indicates the diporphyrin becomes easier to be oxidized. The free-energy changes for charge separation (ΔGₚₛ) was calculated according to the Rehm–Weller method (Eq. (1)), by employing the first oxidation potential of diporphyrin (E₁ox), the first reduction potential of SWNTs (E₁red), and the singlet excitation energy of [H₂Por]₂-ref (ΔE₀–0) [64]:

\[ \Delta Gₛ = E₁ox - E₁red - \Delta E₀–0 \]  

Herein, ΔE₀–₀ (1.81 eV) was determined by the 0–0* absorption. The ΔGₛ value for generating the radical ion pair [H₂Por]₂•⁺ − SWNTs•− was found to be −1.00 eV, which indicates the possibility of photoinduced charge separation in the nanohybrid. It should be noted that the Coulombic terms in the present donor–acceptor systems are negligible, especially in solvents with moderate or high polarity, because of the relatively long edge-to-edge distance (Re₁ > 1 Å) employed [65–70].

2.5. Transient absorption spectroscopy

Time-resolved transient absorption spectrum, following nanosecond laser pulses, was employed to examine the photodynamics of [H₂Por]₂-SWNTs nanohybrid. It provided evidence for charge separation and allowed us to estimate the charge recombination rates, kₚ. Fig. 7 shows a broad absorption band between 460 and 680 nm, which is the typical absorption of radical cation [H₂Por]₂•⁺ of [H₂Por]₂-SWNTs nanohybrid [50]. Meanwhile, a net decrease was observed around 420, 460, 570, 600, and 650 nm due to [H₂Por]₂•⁺, which are dominated by the ground state absorption of diporphyrin. Therefore, the photoinduced electron transfer process involved from [H₂Por]₂•⁺ to SWNTs and, in turn,
created the \([\text{H}_2\text{Por}]_{2}^{\text{•}+/-\text{SWNTs}^{\text{•}−}}\) state, as shown in Scheme 4. The time-resolved transient absorption spectrum confirmed the existence of electron transfer. The lifetime of the charge separation state \([(\text{H}_2\text{Por})_{2}^{\text{•}*+/-\text{SWNTs}^{\text{•}−}})] \) was evaluated to be 145 ns from transient absorption kinetics measurement at 620 nm (Fig. 7), and the \(k_{\text{CR}}\) was calculated to be \(6.9 \times 10^6\) S\(^{-1}\). However, the CS lifetime of TPP-SWNTs and the corresponding \(k_{\text{CR}}\) were determined to be 57 ns and \(1.8 \times 10^7\) S\(^{-1}\) separately. The significant decrease of charge recombination rate, compared to TPP-SWNTs nanohybrid, makes it more feasible to build photovoltaic device.

### 3. Experimental

#### 3.1. Instruments and measurements

UV–vis spectra were recorded on a VARIAN Cary 300 spectrophotometer using a quartz cell with a path length of 10 mm. Fluorescence spectra were obtained with a Cary Eclipse spectrometer. FTIR spectra were obtained with a BRUKER TENSOR 27.

Fig. 7. Nanosecond transient absorption spectra of TPP-SWNTs (A) and \([\text{H}_2\text{Por}]_2\)-SWNTs (B) observed by laser irradiation at 532 nm in THF. The insets showed the time profiles of absorbance at 620 nm.

Instrument. All IR samples were prepared as films on pellets of spectroscopic grade KBr with solution in CHCl₃. Raman spectra were measured by a Renishaw via Raman microscope at room temperature with the 514.5 nm line of an Ar ion laser as an excitation source. Mass spectra were recorded on a FTICR-MS using CH₄/D₂O as the internal standard. XPS spectra were recorded using a Kratos Axis Ultra DLD spectrometer employing a monochromated Al-Ka X-ray source (hν = 1486.6 eV), hybrid (magnetic/electrostatic) optics and a multi-channel plate and delay line detector (DLD). All XPS spectra were recorded using an aperture slot of 300 μm × 700 μm, survey spectra were recorded with a pass energy of 160 eV, and high resolution spectra with a pass energy of 40 eV. Transmission electron microscope (TEM) images were obtained on a FEI TECNAL-20 instrument operated at 100 kV. Sample preparation involved sonication in THF for 30 min and dropping the resulting suspension onto carbon-coated copper grids. Redox potentials were measured by cyclic voltammetry on a BAS electrochemical analyzer model 660. All experiments were carried out using a conventional three-electrode system employing a glassy carbon electrode as the working electrode, Ag/Ag⁺ electrode as the reference electrode, and a Pt wire as the counter electrode. The redox potentials were measured by cyclic voltammetry in ODCB, using 0.04 M n-Bu₄NPF₆ as supporting electrolyte with a scan rate of 100 mV s⁻¹. Nanosecond transient absorption measurements were carried out using the third (532 nm) harmonic of Q-switched Nd:YAG laser (Continuum Surelite i, fwhm 7 ns) as excitation source and a Germanium Photodiode (Edinburgh Lp900) was used as a detector. All of the sample were dissolved in THF, and deaerated with Ar bubbling for 30 min at room temperature.

3.2. Materials

The pristine carbon nanotube was purchased from Shenzhen Nanotech Port Co., individual tubes of SWNTs have a diameter range of <2 nm. All of solvents were purified according to standard methods. Acetonitrile, o-dichlorobenzene (ODCB), chloroform, dichloromethane, 1,2-dichloroethane and N,N-dimethylformamide (DMF) were distilled from calcium hydride before use. THF and toluene were dried and distilled from sodium. All other chemicals (AR) obtained from commercial sources were used without any further purification.

3.3. Preparation

5,15-Di[3,5-di-tert-butyl]phenylporphinozinc (3-Zn).

5-(p-aminophenyl)-10,15,20-triphenylporphyrin (TPP-NH₂), were prepared according to the literature [72,73].

3.3.1. Synthesis of 5,15-di[3,5-di-tert-butyl]phenyl-10-(4-nitrophenyl)porphyrin (1)

To a solution of 4-nitrophenyldipyrromethane (1.06 g, 3.2 mmol) and 3,5-di-tert-butylbenzaldehyde (1.21 g, 5.6 mmol) in 950 mL dry dichloromethane pumped with N₂ for 15 min, TFA (0.73 g, 6.4 mmol) was added, then dipyrromethane (0.41 g, 2.8 mmol) in 75 mL dry dichloromethane was added dropwise for 30 min. The mixture was stirred at room temperature for 1 h, then treated with DDQ (1.41 g, 6.2 mmol) and stirred for another 2 h. Removal of solvent and chromatography afforded a purple solid (185 mg, 8%). ¹H NMR (CDCl₃): δ 10.28 (s, 1H), 9.38 (d, J = 4.5 Hz, 2H), 9.09 (d, J = 4.5 Hz, 2H), 9.00 (d, J = 4.5 Hz, 2H), 8.76 (d, J = 4.5 Hz, 2H), 8.64 (d, J = 8.7 Hz, 2H), 8.41 (d, J = 8.4 Hz, 2H), 8.11 (d, J = 1.5 Hz, 4H), 7.83 (t, J = 1.5 Hz, 2H), 1.55 (s, 36H), -2.96 ppm (2H).

3.3.2. Synthesis of 5-bromo-15-(4-nitrophenyl)-10,20-di(3,5-di-tert-butyl)phenyl)porphyrin (2)

NBS (5 mg, 0.028 mmol) was added to a stirred solution of 1 (21 mg, 0.026 mmol) in 50 mL CHCl₃/MeOH (9:1) at room temperature. After 10 min, the reaction was quenched with acetone (2 mL). Removal of solvent and the residue was crystallized with CHCl₃/MeOH to afford the product as a purple solid (21 mg, 91%).
1H NMR (CDCl3): δ 9.70 (d, J = 4.8 Hz, 2H), 8.96 (d, J = 4.8 Hz, 2H), 8.88 (d, J = 4.8 Hz, 2H), 8.69 (d, J = 4.8 Hz, 2H), 8.63 (d, J = 8.4 Hz, 2H), 8.37 (d, J = 8.4 Hz, 2H), 8.05 (d, J = 1.6 Hz, 4H), 7.83 (t, J = 1.6 Hz, 2H). 1.54 (s, 36H), −2.72 ppm (s, 2H).

3.3.3. Synthesis of ZnII-free base hybrid diporphyrin 5

Bromoporphyrin 2 (119 mg, 0.134 mmol), porphyrin boronate 4 (117.5 mg, 0.134 mmol), Cs2CO3 (65.6 mg, 0.201 mmol), and Pd[PPh3]4 (15.5 mg, 0.0134 mmol) were dissolved in a mixture of dry DMF (9 mL) and dry toluene (18 mL). The solution was deoxygenated with anhydrous Na2SO4. The desiccant was filtered off and the filtrate was treated with TFA at room temperature for an hour. The mixture was evaporated off on an evaporator and the residue was separated by silica gel chromatography with CH2Cl2 to give purple solid.

3.3.4. Synthesis of meso-meso linked diporphyrin 7

ZnII-free base hybrid diporphyrin 5 (142 mg, 0.091 mmol) was dissolved in CH2Cl2 (13 mL) and methanol (9 mL), to which 5% Pd/C (54 mg) was added. Then, NaBH4 (47 mg, 1.175 mmol) was added to the solution by portions, and the resulting mixture was stirred for 2 min at room temperature. Pd/C was filtered off and the resulting filtrate was washed with water and the organic layer was dried over anhydrous Na2SO4. The desiccant was filtered off and the filtrate was treated with TFA at room temperature for an hour. The mixture was washed with saturation Na2CO3 and the organic layer was dried with anhydrous Na2SO4. Removal of solvent and chromatography afforded a purple solid (142 mg, 68%). 1H NMR (CDCl3): δ 10.41 (s, 1H), 9.51 (d, J = 4.8 Hz, 2H), 9.20 (d, J = 4.8 Hz, 2H), 8.97 (d, J = 4.8 Hz, 2H), 8.81 (d, J = 4.8 Hz, 2H), 8.79 (d, J = 4.8 Hz, 2H), 8.69 (d, J = 4.8 Hz, 2H), 8.60 (d, J = 4.8 Hz, 2H), 8.50 (d, J = 8.4 Hz, 2H), 8.19 (d, J = 4.8 Hz, 2H), 8.11 (d, J = 1.6 Hz, 4H), 8.06 (d, J = 1.6 Hz, 4H), 8.03 (d, J = 4.8 Hz, 2H), 7.72 (t, J = 1.6 Hz, 2H), 7.70 (t, J = 1.6 Hz, 2H), 1.45 (d, J = −13.2 Hz, 72H), −2.15 ppm (s, 2H); ESI-MS m/z: 1554.83 ([M+H]+); calcd for C102H108N9O2Zn 1554.79.

3.3.5. Synthesis of porphyrin–SWNTs nanohybrids TPP–SWNTs

ODA-SWNTs (6.0 mg) was sonicated for 15 min in ODCB (7.5 mL). To this suspension, TPP-NH2 (10 mg, 0.016 mmol) in acetonitrile (2.0 mL) was added. Bubbled nitrogen for 15 min, isoamyl nitrite (5 μL, 0.037 mmol) was quickly added and the suspension was stirred in the dark at 70 °C for 48 h. During the period, another 90 mg (0.060 mmol) TPP-NH2 and 25 μL (0.19 mmol) isoamyl nitrite were added in 5 portions (total 5 × 18 mg) and 5 × 5 μL isoamyl nitrite) to ensure a high degree of functionalization. The suspension was diluted with 10 mL DMF, filtered over a nylon membrane (0.1 μm), and washed repetitively with DMF. The filtered product was sonicated in DMF and filtered repeatedly. Ultimately, the product was washed with CH2Cl2 and dried in vacuum at 80 °C for 10 h to give [H2Por]2–SWNTs (6.1 mg).

4. Conclusion

In conclusion, we have prepared covalently linked [H2Por]2–SWNTs nanohybrid for the first time, where meso-meso linked diporphyrin is successfully incorporated into a charge separation unit as a photosynthetic electron-transfer model. The nanohybrid reveals photoinduced electron-transfer from the diporphyrin excited singlet state to the SWNTs, which resulted in the generation of [H2Por]2**–SWNTs* radical ion pair with 145 ns lifetime. It should be emphasized here that the CS lifetime of the nanohybrid has been prolonged substantially by replacing monoporphyrin with diporphyrin. The present results demonstrate that meso-meso linked diporphyrin is an outstanding electron donor to build SWNTs involving light-energy conversion and photovoltaic devices.
